

How confidence interval is estimated

Confidence interval is $[c - \Delta, c]$, where

$$c(W_L, W_R) = \frac{2 \operatorname{cov}(W_L, W_R)}{\operatorname{var} W_L + \operatorname{var} W_R} \in [-1, 1]$$

$$\Delta(W_L, W_R) = \alpha \frac{4 |c(W_L, W_R)|}{\operatorname{var} W_L + \operatorname{var} W_R} + \beta, \quad \alpha, \beta \geq 0$$

$B_{\bar{O}}$ mismatches in non-occluded region

$B_{\bar{T}}$ mismatches in textureless regions

$B_{\mathcal{D}}$ errors at disparity discontinuities

Generalization to sparse matching / tracking

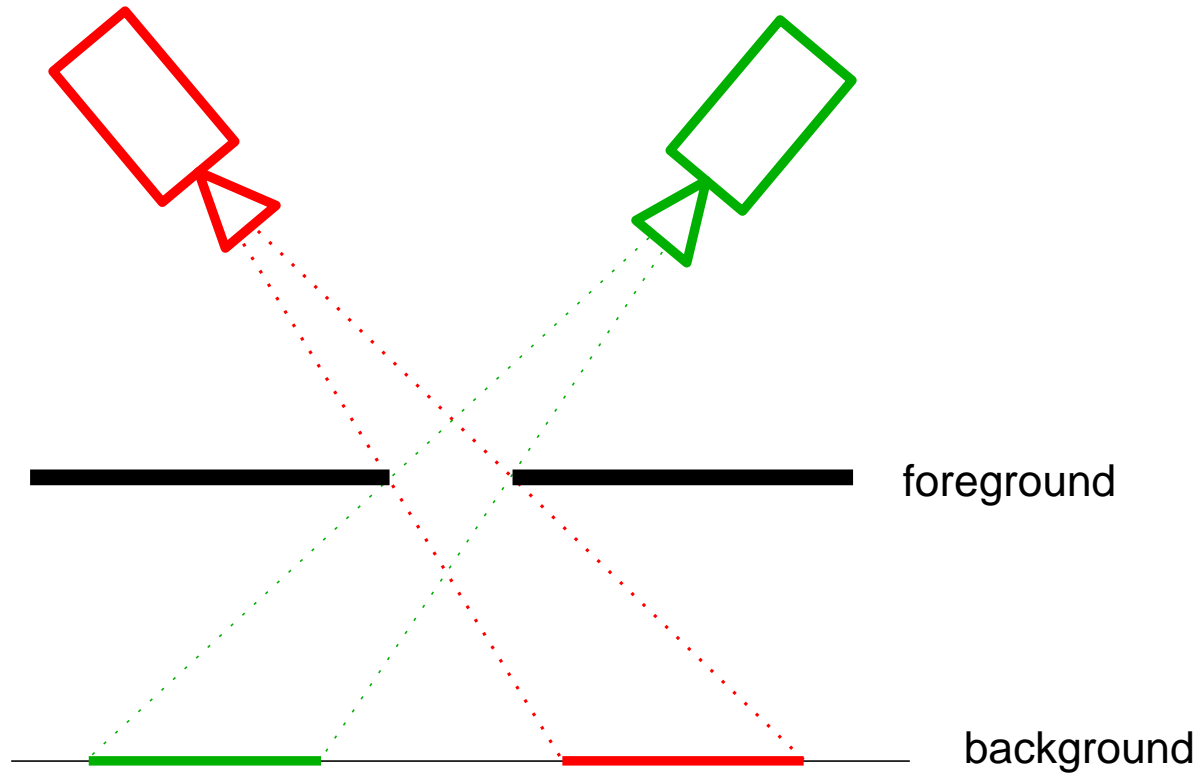

- ◆ sparse / dense / points / point sets / regions
- ◆ X -zone can be always constructed
- ◆ more dense zone improves error rate exponentially

Necessary ingredients

1. match pre-selection (optional; improves speed)
2. **inhibition zone** for each tentative match
3. discriminable **signature compatibility** function
4. confidence interval for signature compatibility (optional; improves error rate)

Binocular peaking through a narrow slit is difficult

Binocular peaking through a narrow slit is difficult

- ◆ Adding cameras may not help!

Binocular peaking through a narrow slit is difficult

- ◆ Adding cameras may not help!
- ◆ Continuity model fails.

Binocular peaking through a narrow slit is difficult

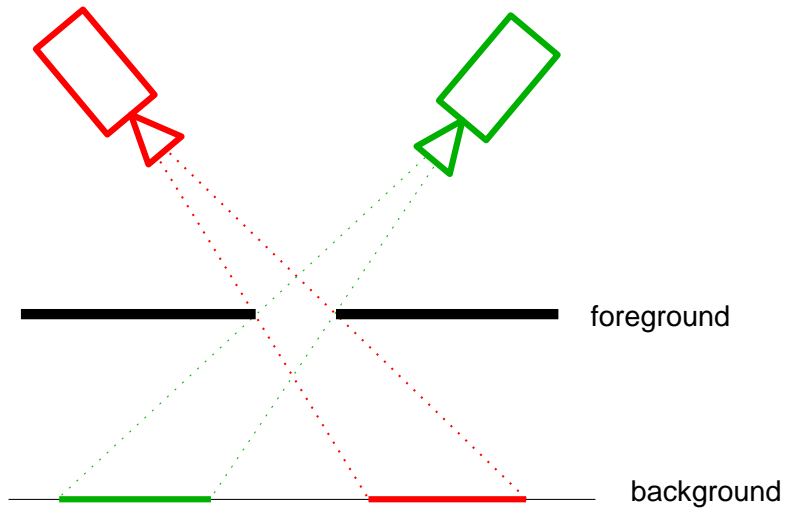

- ◆ Adding cameras may not help!
- ◆ Continuity model fails.
- ◆ Self-occlusion model fails.

Binocular peaking through a narrow slit is difficult

- ◆ Adding cameras may not help!
- ◆ Continuity model fails.
- ◆ Self-occlusion model fails.
- ◆ Detecting matches at a confidence level **may** save it. (But no repetitive texture is allowed)
